## The Guide

This is my recommended path for learning Haskell.

Something to keep in mind: *don't sweat the stuff you don't understand immediately*. Just keep moving.

## Community

Our IRC channel is #haskell-beginners on Freenode.

IRC web client [here](#).

The haskell [mailing lists](#).

## Community Guidelines

[Letter to a Young Haskell Enthusiast](#)

Be nice above all else!

## What are Haskell, GHC, and Cabal?

Haskell is a programming language as laid out in the reports, most recent one being in 2010. The report is available as the [onlinereport](#).

### GHC

[GHC](#) is the most popular way to work in the Haskell language. It includes a compiler, REPL (interpreter), package management, and other things besides.

### Cabal

[Cabal](#) does project management and dependency resolution. It's how you'll install projects, typically into their own sandbox.

Cabal is equivalent to Ruby's Bundler, Python's pip, Node's NPM, Maven, etc. GHC manages packaging itself, Cabal chooses what versions to install.

# Getting set-up

## Ubuntu

[This PPA](#) is excellent and is what I use on all my Linux dev and build machines.

Specifically:

```
$ sudo apt-get update
$ sudo apt-get install python-software-properties # v12.04 and below
$ sudo apt-get install software-properties-common # v12.10 and above
$ sudo add-apt-repository -y ppa:hvr/ghc
$ sudo apt-get update
$ sudo apt-get install cabal-install-1.20 ghc-7.8.3 happy-1.19.4 alex-3.1.3
```

Then add the following to your \$PATH (bash\_profile, zshrc, bashrc, etc):

- ~/.cabal/bin
- /opt/cabal/1.20/bin
- /opt/ghc/7.8.3/bin
- /opt/happy/1.19.4/bin
- /opt/alex/3.1.3/bin

*Optional:* You could also add `.cabal-sandbox/bin` to your path. Code that you are actively developing will be available to you from the command line. This only works when your current working directory is a cabal sandbox.

## Debian

### GHC Repository for debian stable

If you use Debian stable, it is easier to use <http://deb.haskell.org/>. To use it:

- Add the line `deb http://deb.haskell.org/stable/ ./` to `/etc/apt/sources.list`

```
## Add the key to avoid warnings
$ GET http://deb.haskell.org/deb.haskell.org.gpg-key | apt-key add -
$ sudo apt-get update
$ sudo apt-get install ghc-7.8.3 happy alex cabal-install
```

### Using Ubuntu PPA

If you're not using stable, you can follow the same steps as Ubuntu, but will have to execute an additional command. Immediately after `sudo add-apt-repository -y ppa:hvr/ghc` is executed run:

```
$ sudo sed -i s/jessie/trusty/g /etc/apt/sources.list.d/hvr-ghc-jessie.list
```

For other Debian versions, just replace all occurrences of `jessie` with your version name in the command above.

If, for some reason, the file `/etc/apt/sources.list.d/hvr-ghc-jessie.list` does not exist, then `/etc/apt/sources.list` should contain a line like this:

```
deb http://ppa.launchpad.net/hvr/ghc/ubuntu jessie main
```

Replace `jessie` with `trusty` in this line.

## Manual compilation

You can follow [this](#) guide written for Mac OS X:

Notes:

- Set your prefix accordingly when configuring ghc.
- Instead of grabbing the cabal-install binary, grab the source and then run bootstrap.sh script.

## Fedora 21

To install Haskell 7.8.4 from the unofficial repo (Fedora 22+ will include it in the official one):

```
$ sudo yum-config-manager --add-repo \  
> https://copr.fedoraproject.org/coprs/petersen/ghc-7.8.4/repo/fedora-21/petersen-ghc-7.8.4-fedora-21.repo  
$ sudo yum install ghc cabal-install
```

As stated in [petersen/ghc-7.8.4 copr page](#) this ghc cannot be installed in parallel with Fedora/EPEL ghc.

## Arch Linux

To install Haskell from the official repos on Arch Linux, run

```
$ sudo pacman -S cabal-install ghc happy alex haddock
```

## Gentoo

On Gentoo, you can install the individual components of the Haskell Platform through Portage. If you use `ACCEPT_KEYWORDS=arch` (as opposed to `ACCEPT_KEYWORDS=~arch`), Portage will install ancient versions of the various Haskell things. With that in mind, iff you use `ACCEPT_KEYWORDS=arch`, add the following to `/etc/portage/package.keywords`.

```
dev-haskell/cabal-install  
dev-lang/ghc
```

Once that is done,

```
$ emerge -jav dev-lang/ghc dev-haskell/cabal-install
```

Gentoo keeps a “stable” (read: old) version of `cabal-install` in the Portage tree, so you’ll want to use `cabal-install` to install the more recent version. Note that the backslashes are intentional.

```
$ \cabal update           # The backslashes  
$ \cabal install cabal-install # are intentional
```

You have now installed `cabal` on a global scale with `portage`, and locally in your home directory with `cabal-install`. The next step is to make sure that when you run `cabal` in a terminal, your shell will run the up-to-date version in your home directory. You will want to add the following lines to your shell’s configuration file:

```
PATH=$PATH:$HOME/.cabal/bin  
alias cabal="$HOME/.cabal/bin/cabal"
```

If you don't know what your shell is, more than likely, your shell is Bash. If you use Bash, the file you will edit is `~/.bashrc`. If you use Z-shell, the file is `~/.zshrc`. You can run the following command to find out what your shell is.

```
echo $SHELL | xargs basename
```

I use zsh, so that command outputs zsh when I run it.

Once you do all of that, you'll want to install the additional tools `alex` and `happy`.

```
$ cabal install alex happy
```

Congratulations! You now have a working Haskell installation!

## Mac OS X

### 10.9

Install the [GHC for Mac OS X](#) app, which includes GHC and Cabal. It provides instructions on how to add GHC and Cabal to your path after you've dropped the `.app` somewhere.

### 10.6-10.8

Do the binary distribution install described below with [this tarball](#).

## Windows

- The [windows minimal GHC installer](#) is able to compile `network` et al. Technically in beta but should work for the purposes of anybody reading this guide.

Don't forget to run the installer as administrator as it will want to install in your Program Files.

## Other Linux users

Download the latest binary distributions for cabal and ghc:

- [GHC](#).
- [Cabal](#).

**Detailed manual install guide for Mac OS X** You don't need this if you use the .app, but if it doesn't work for you, try [this](#) with the binary distribution.

## Primary Courses

### Yorgey's cis194 course

*Do this first*, this is the primary way I recommend being introduced to Haskell.

Available [online](#).

[Brent Yorgey](#)'s course is the best I've found so far. This course is valuable as it will not only equip you to write basic Haskell but also help you to understand parser combinators.

The only reason you shouldn't start with cis194 is if you are not a programmer or are an inexperienced one. If that's the case, start with [Thompson's book](#) and transition to cis194.

---

## NICTA course

This is the course I recommend doing after Yorgey's cis194 course

Available on github [here](#).

This will reinforce and give you experience directly implementing the abstractions introduced in cis194, this is practice which is *critical* to becoming comfortable with everyday uses of Functor/Applicative/Monad/etc. in Haskell. Doing cis194 and then the NICTA course represents the core recommendation of my guide and is how I teach everyone Haskell.

---

## Supplementary Course cs240h

Provides more material on intermediate topics

Available [online](#).

This is [Bryan O'Sullivan](#)'s online course from the class he teaches at Stanford. If you don't know who he is, take a gander at half the libraries any Haskell application ends up needing and his name is on it. Of particular note if you've already done the Yorgey course are the modules on phantom types, information flow control, language extensions, concurrency, pipes, and lenses.

---

## Reference material for the three courses

[Learn You a Haskell for Great Good \(LYAH\)](#) and [Real World Haskell](#) (Thanks bos!) are available online.

I recommend RWH as a reference (thick book). The chapters for parsing and monads are great for getting a sense for where monads are useful. Other people have said that they've liked it a lot. Perhaps a good follow-up for practical idioms after you've got the essentials of Haskell down?

### What does that `<- / do / list comprehension syntactic sugar` do?

Excellent [article](#).

### For understanding list and fold

- [Explain List Folds to Yourself](#)

### For learning some common typeclasses

Useful for understanding Functor, Applicative, Monad, Monoid and other typeclasses in general but also some Haskell-specific category theory:

- The [Typeclassopedia](#)

## Understanding basic Haskell error messages

- [Understanding basic error messages](#)
- 

## Laziness, strictness, guarded recursion

- Marlow's [book](#) about parallelism and concurrency has one of the best introductions to laziness and normal form I've found. Use other material too if it doesn't stick immediately.
- [More points for lazy evaluation](#)
- [Oh my laziness!](#)
- SO question '[Does haskell have laziness?](#)'
- [Johan Tibell's](#) slides from a talk on [reasoning about laziness](#).

## Brief demonstration

```
let a = 1 : a -- guarded recursion, (:) is lazy and can be pattern matched.
let (v : _) = a
> v
1
> head a -- head a == v
1
```

```
let a = 1 * a -- not guarded, (*) is strict
> a
*** Exception: <<loop>>
```

## IO

- Evaluation order and State tokens
- Unraveling the mystery of the IO monad.
- First class “statements”.
- [Haddocks for System.IO.Unsafe.unsafePerformIO](#) Read the docs and note implementation of unsafeDupablePerformIO

Comment from Reddit thread by [glaebhoerl](#)

Interesting side note: GHC needs to hide the state token representation behind an abstract IO type because the state token must always be used linearly (not duplicated or dropped), but the type system can't enforce this. Clean, another lazy Haskell-like language, has uniqueness types (which are like linear types and possibly different in ways I'm not aware of), and they expose the World-passing directly and provide a (non-abstract) IO monad only for convenience.

## Monads and monad transformers

Do not do these until you understand typeclasses, Monoid, Functor, and Applicative!

Implement the standard library monads ( List, Maybe, Cont, Error, Reader, Writer, State ) for yourself to understand them better. Then maybe write a monadic interpreter for a small expression language using [Monad Transformers Step by Step](#) paper (mentioned in 'monad transformers' below).

Writing many interpreters by just changing the monad to change the semantics can help convey what's going on.

- [This talk](#) by Tony excellently motivates monad transformers.

Also, reimplement `Control.Monad`. Functions like `mapM` or `sequence` are good opportunities to practice writing generic monadic code.

The NICTA course can be used as a guide to this process, which will also involve writing your own `Applicative` as well.

- [My dotfiles](#)
- [Chris Done's emacs config](#)

### Vim

- [Vim page on haskellwiki](#)
- [Haskell-vim-now](#)
- [A vim+haskell workflow](#)
- [GHC-Mod](#)
- [GHC-Mod vim plugin](#)
- [Hindent](#)

## Sublime Text

- [SublimeHaskell](#)

## FAQ and working with Cabal

### Fantastic FAQ

In addition to being an amazing guide for all kinds of things such as GADTs, this also covers some useful basics for Cabal

- [What I wish I knew when learning Haskell](#) also on github [here](#).

### Cabal guidelines

Cabal Hell was a problem for Haskell users before the introduction of sandboxes. Installing outside of a sandbox will install into your user package-db. This is *not* a good idea except for foundational packages like Cabal, alex, and happy. Nothing else should be installed in the user or global package-dbs unless you know what you're doing.

Some best practices for avoiding cabal hell are available [here](#).

To experiment with a package or start a project, begin by doing `cabal sandbox init` in a new directory.

Put briefly:

- Always use sandboxes for installing new packages, building new or existing projects, or starting experiments
- Use `cabal repl` to start a project-scoped ghci instance

The sandbox-based approach I suggest should avoid package-dependency problems, but it's incompatible with the way the Haskell Platform provides pre-built packages. If you're still learning Haskell and don't understand how `ghc-pkg` and `Cabal` work, *avoid platform* and instead use the install instructions earlier in the guide.

## Stackage

For any users (usually Yesod users) that have build problems, consider Stackage.

- A good summary of Stackage is [here](#).

In the author's opinion, Stackage is usually more useful than `cabal freeze`.

## Hoogle and Haddock

### Search code by type signature

The [Hoogle search engine](#) can search by type.

For example, look at the search results for `(a -> b) -> [a] -> [b]` [here](#).

Also hosted by `fpcomplete` [here](#).

Also [Hayoo](#) (which has all of `hackage` enabled for search by default).

### Setting up your own local instance of Hoogle

Take a look [here](#).

## Haddock

1. [Fix your hackage documentation](#)
2. [Hackage documentation v2](#)

Note that these posts are *slightly out of date*: for example, now Hackage sports shiny new info with documentation info and build status.

## What you really need to know

In order to have haddocks include documentation for related packages, you have to set `documentation: True` in your `~/.cabal/config`. If it was left on the default (`False`) or set to `False`, you'll have to delete all your packages and reinstall before generating haddocks.

The other thing to keep in mind is that due to the way the `$pkg` parameter gets interpolated *by* cabal, not by you, the `html-location` and `content-location` parameters *must be in single quotes* and entered into a shell or contained in a shell script. They will not work in a Makefile, because it will think they are Make variables!

```
#!/usr/bin/env sh
```

```
# You can write it one one line by skipping the backslashes
cabal haddock --hoogle --hyperlink-source \
  --html-location='http://hackage.haskell.org/package/$pkg/docs' \
  --contents-location='http://hackage.haskell.org/package/$pkg'
```

## TravisCI

If you're as big a fan of [TravisCI](#) as I am, then I *strongly* recommend you take a look at [multi-ghc-travis](#) by as the basis of the `travis.yml` for your Haskell projects.

## Frontend/JavaScript

We have an embarrassment of riches! There are three main choices I would recommend:

- [Haste](#) a Haskell to JavaScript compiler
- The [compiler](#) on github.
- An excellent [demo](#) of Haste with an example project.
- [GHCJS](#)
- [GHCJS Introduction](#)
- [Functional Reactive Web Interfaces with GHCJS and Sodium](#)
- [PureScript](#)
- Not strictly Haskell like Haste and GHCJS, but a popular choice among Haskellers
- Written in and inspired by haskell
- Try purescript in you browser [here](#)
- Great guide for [getting started](#)

## Which frontend language do I use?

GHCJS and Haste are both fully Haskell. GHCJS will work with more Haskell packages than Haste, but this doesn't affect a lot of frontend projects. PureScript isn't Haskell at all, so direct code sharing with your backend will not work.

GHCJS has the fattest runtime payload overhead at about 100kb (luite is working on this). Haste and PureScript are competitive.

PureScript has the best JS tooling integration (uses gulp/grunt/bower), GHCJS and Haste integrate better with Haskell's tooling (Cabal).

All three are great choices and will work for most frontend projects.

## For a more thorough understanding of laziness, NF, WHNF

- [Notes on lambda calculus.](#)

## Research papers about lazy lambda calculi

- [A call by need lambda calculus.](#)
- [Demonstrating Lambda Calculus Reduction](#)
- [The lazy lambda calculus.](#)
- [Lazy evaluation of Haskell](#)

## Parallelism/Concurrency

- [Parallel and Concurrent Programming in Haskell](#). This book by Simon Marlow is probably the best I've ever read on the topics of Parallelism and Concurrency.
- A thorough [walk-through](#) on testing & incremental development of a multi-threaded application in Haskell.
- [Functional Reactive Programming](#)

## Lenses and Prisms

After you're comfortable with Haskell, strongly consider learning Lenses and Prisms, even if just as a "user". You don't need to understand the underlying category for it to be useful.

People vastly overestimate the difficulty of using Lens. Anybody comfortable with Functor/Foldable/Traversable (or even just the first one) can leverage lenses and prisms to make their life happier.

If you've ever done something like: `(fmap . fmap)` you were "lensing" in your head.

I recommend these two tutorials/introductions:

- [A little lens starter tutorial](#)
- [Lens: Lenses, Folds and Traversals](#)

Look here for more information: [Lens package on hackage](#).

## Recursion Schemes

Some of the crazy \*-morphism words you've heard are actually about recursion. NB - before tackling this material you should know how to implement foldr for lists and at least one other data structure, such as a tree. (folds are catamorphisms) Knowing how to implement an unfold (anamorphism) for the same will round things out a bit.

This material dovetails with traversable and foldable.

- [An introduction to recursion schemes](#)
- [Don't fear the cat](#) - Good demonstration of how hylomorphism is the composition of cata and ana.
- [Recursion Schemes](#) - This field guide is excellent.
- [Functional Programming with Bananas, Lenses, Envelopes and Barbed Wire](#)
- [Catamorphisms](#)

## GHC Core and performance tuning

- [Write Haskell as Fast as C](#)
- [GHC Wiki: CoreSyn Type.](#)
- [Hackage: GHC Core.](#)
- [SO Question: Reading GHC Core.](#)
- [Haskell as fast as C.](#)
- [Real World Haskell, Chapter 25: Profiling and Optimizations.](#)

## Graph algorithms and data structures

- The [fgl package](#) particularly the purely functional shortest path [algorithms](#).
- [Inductive graphs and Functional Graph Algorithms](#).
- [FGL/Haskell - A Functional Graph Library](#).
- [Data.Graph source from Containers package](#).
- The [graphs package](#).
- [SO question about PHOAS](#)
- [PHOAS for free](#).
- [Tying the Knot](#).
- [Hackage: dag](#).

## Type and Category Theory

*Not needed to actually write Haskell, just for those interested!*

If you want to follow up on type and category theory:

- [Catster's Guide](#) and [Catster's Guide 2](#)
- The [haskell wikibook](#) has nice diagrams
- [Category Theory](#) on haskellwiki, also has good links to other resources

- [Categories from scratch](#), Includes some practical examples.
- Pierce's [Great Works in PL](#) list.

## Books

- [Quora Question: What is the best textbook for category theory?](#) Kmett's recommendations
- [Awodey](#) and [MacLane](#). The standard textbooks on category theory.
- [Harper's Practical Foundations for Programming Languages](#) is the best PL focused intro to type theory I've read.
- [Type theory and Functional Programming](#).

## Stephen's Nifty "How to get to monad" posts

- [Adjunctions](#).
- [Monads](#).

## Other theoretical topics

### Parametricity, ad-hoc vs. parametric polymorphism, free theorems

- [Parametricity](#).
- [TeX sources](#) for the above talk.

- [Making ad-hoc polymorphism less ad-hoc.](#)
- [Theorems for Free!](#)

## Initial and Final, DSLs, Finally Tagless

- [Final Encodings, Part 1: A Quick Demonstration.](#)
- [Transforming Polymorphic Values.](#)
- [GADTs in Haskell 98.](#)
